# Package 'behavr'

August 30, 2017

Title Cannonical Data Structure for Behavioural Data
<b>Date</b> 2017-07-25
Version 0.3.0.9003
Description  Implements an S3 class based on data.table to store and process efficiently ethomics (high-throughput behavioural) data.
Imports data.table, hms, methods
Suggests testthat
License GPL-3
Encoding UTF-8
LazyData true

2 behavr

behavr

An S3 class, based on data.table, to store ethomics data

#### **Description**

In modern behavioural biology, it is common to record long time series of several *variables* (such as position, angle, fluorescence and so on) on multiple individuals. In addition to large multivariate time series, each individual is associated with a set of *metavariables* (i.e. sex, genotype, treatment and lifespan), which, together, form the *metadata*. Metavariables are crucial in so far as they generally "contain" the biological question. During analysis, it is therefore important to be able to access, alter and compute interactions between both variables and metavariables. behave is a class that facilitates manipulation and storage of metadata and data in the same object. It is designed to be both memory-efficient and user-friendly. For instance, it abstracts joins between data and metavariables.

## Usage

```
behavr(x, metadata)
setbehavr(x, metadata)
is.behavr(x)
```

#### **Arguments**

x data.table containing all measurments
metadata data.table containing the metadata

## **Details**

Both x and metadata should have a **column set as key** with **the same name** (typically named id). behavr() copies x, whilst setbehavr() uses reference. metadata is always copied.

#### See Also

- the behavr webpage
- data.table on which behave is based
- xmv to join metavariables
- rejoin to join all metadata
- bind\_behavr\_list to merge several behavr tables

bind\_behavr\_list 3

bind\_behavr\_list

Put together a list of behavr tables

## **Description**

Bind all rows of both data and metadata from a list of behavr tables into a single behavr table. It checks keys, number and names of columns are the same across all data. In addition, it forbids to bind metadata if it would result in duplicates (same id in two different metadata)

## Usage

```
bind_behavr_list(1)
```

## **Arguments**

1

list of behavr

## Value

a single behavr object

#### See Also

• behavr – the documentation of the behavr object

bin\_apply

```
d_all <- bind_behavr_list(list(d1, d2))
print(d_all)</pre>
```

bin\_apply

Bin a variable (typically time) and compute an aggregate for each bin

#### **Description**

This function is typically used to summarise (i.e. computing an aggreate of) a variable (y) for bins of a another variable x (typically time).

#### Usage

```
bin_apply(data, y, x = t, x_bin_length = mins(30), wrap_x_by = NULL,
   FUN = mean, string_xy = FALSE, ...)
bin_apply_all(data, ...)
```

#### **Arguments**

```
data.table or behavr table (see details)

y variable to be aggregated

x variable to be binned

x_bin_length length of the bins (same unit as 'x")

wrap_x_by numeric value defining wrapping period. NULL, the defsult, means no wrapping.

FUN function used to aggregate (e.g. mean, median, sum and so on)

string_xy logical whether the names of the variables are quoted

... additional arguments to be passed to FUN
```

#### **Details**

bin\_apply expects data from a single individal. bin\_apply\_all works on multiple individuals identified by a unique key. wrapping is typically used to compute averages accross several periods. For instance,wrap\_x\_by = days(1), means bins will aggreate values accross several days. In this case, the resulting x can be interpreted as "time relative to the onset of the day" (i.e. ZT).

meta 5

meta

Retreive and set metadata

## **Description**

This function returns the meta data from a behavr object

## Usage

```
meta(x)
setmeta(x, new)
```

## **Arguments**

```
x behavr object
new a new metadata table
```

## Value

a data.table representing the metadata in x

## See Also

behavr to generate a behavr object, xmv to map metavariables to data

6 rejoin

```
d <- behavr(data, met)
## show metadata
meta(d)
# same as:
d[meta = TRUE]
## set metadata
m <- d[meta = TRUE]
# only id > 2 is kept
setmeta(d, m[id < 3])
meta(d)</pre>
```

print.behavr

Print and summarise a behavr table

## **Description**

Print and summarise a behavr table

## Usage

```
## S3 method for class 'behavr'
print(x, ...)
## S3 method for class 'behavr'
summary(object, detailed = F, ...)
```

## **Arguments**

x, object behave table... arguments passed on to further methoddetailed whether summary should be consise

## See Also

- behavr to generate x
- print.default
- summary.default

rejoin

Join data and metadata

## Description

This function joins the data of a behavr object to its metadata. When dealing with large data sets, it is preferable to keep metadata and data separate until a summary of data is computed. Indeed, joining many metavariables to very long time series may result in unnecessary large memory usage.

stitch\_on 7

#### Usage

```
rejoin(x)
```

## Arguments

Χ

behavr object

#### Value

a data.table

#### See Also

behavr to generate a behavr object

## **Examples**

stitch\_on

Sticth behavioural data by putting together individuals belonging to different experiments on the basis of a user defined id

## **Description**

This functions can merge rows of data from the same individual, that was recorded over multiple experiments. A common scenario is when an experiment is interrupted (the individuals could be, for instance, shuffled), and a new recording is started. Stitching assumes the users has defined a *unique id* in the metadata that referes to a spefific individual. Then, if any data that comes form the same unique id, it is merged.

## Usage

```
stitch_on(x, on, time_ref = "datetime", use_time = F, time_variable = "t")
```

8 stitch\_on

#### **Arguments**

X	behavr object
on	name of a metavariable serving as a unique id (per individual)
time_ref	name of a metavariable used to align time (e.g. "date", or "datetime")
use_time	whether to use time as well as date
time_variable	name of the variable describing time

#### **Details**

When several ids match a unique id (several experiments), the first (in time) experiment is used to generate the new id. The data from the following one(s) will be added with a time lag equls to the difference between the time\_ref. When data is not aligned to circadian time, it makes sense to set use\_time to TRUE. Otherwise, the assuption is that the time is already aligned to a circadian reference, so only the date is used.

#### Value

a behavr table

#### See Also

behavr to generate a behavr object

```
set.seed(1)
met1 <- data.table::data.table(uid = 1:5,id = 1:5,</pre>
                                 condition = letters[1:5],
                                 sex=c("M","M","M","F", "F"),
                                 key="id")
met2 <- data.table::data.table(uid = 1:4,id = 6:9,</pre>
                                 condition = letters[1:4],
                                 sex=c("M","M","M","F"),
                                 key="id")
met1[, datetime := as.POSIXct("2015-01-02")]
met2[, datetime := as.POSIXct("2015-01-03")]
met <- rbind(met1, met2)</pre>
data.table::setkeyv(met, "id")
t <- 1L:100L
data \leftarrow met[,list(t=t, x=rnorm(100), y=rnorm(100), eating=runif(100) > .5), by="id"]
d <- behavr(data,met)</pre>
summary(d)
d2 <- stitch_on(d, on ="uid")</pre>
summary(d2)
```

time\_conversion 9

time\_conversion

Time conversion utilities

#### **Description**

Trivial functions to convert time to seconds – as behavr uses second as a conventionnal unit of time.

#### Usage

```
days(x)
hours(x)
mins(x)
```

## **Arguments**

Х

a numerical vector to be converted in second

#### **Details**

Most functions in the rethomics framewhor will use seconds as a unit of time. It is always preferable to call a function like my\_function(days(1.5)) rather than my\_function(60\*60\*24\*1.5).

## Value

```
number of seconds corresponding to x (1d = 86400s, 1h = 3600s \text{ and } 1\text{min} = 60s)
```

toy\_activity\_data

Generate toy activity and sleep data mimiking Drosophila behaviour in tubes

## Description

This function generates random data that emulates some of the features of fruit fly activity and sleep. This is designed **exclusively to provide material for examples and tests** as it generates "realistic" datasets of arbitrary length.

## Usage

```
toy_activity_data(query = NULL, seed = 1, rate_range = 1/c(60, 10),
  duration = days(5), sampling_period = 10, ...)
toy_ethoscope_data(...)
toy_dam_data(...)
```

10 xmv

#### **Arguments**

query (i.e. a dataframe where every row defines an animal). Typically queries have, at least, the columns experiment\_id and region\_id. The default value (NULL), will generate data for a single animal.

seed random seed used (see set.seed)

rate\_range a parameter defining the boundaries of rate at which animals wake up. It will be uniformely distributed between animals, but fixed for each animal.

duration length (in seconds) of the data to generate

sampling\_period sampling period (in seconds) of the resulting data

... additional arguments to be passed to simulate\_animal\_activity

#### Value

a behavr table with the query columns as metavariables. In addition to id and t columns different methods will output different variables:

- toy\_activity\_data will have asleep and moving (1/10s)
- toy\_dam\_data will have activity (1/60s)
- toy\_ethoscope\_data will have xy\_dist\_log10x1000, has\_interacted and x (2/1s)

#### **Examples**

xmv

Expand a metavariable and map it against the data

#### **Description**

This function eXpands a MetaVariable from a parent behave object. That is, it matches this variable (from metadata) to the data *by id*.

xmv 11

#### Usage

```
xmv(var)
```

#### **Arguments**

var

the name of the variable to be extracted

#### **Details**

This function *can only be called within between the* [] *of a parent* behave object. It is intended to facilitate operations between data and metadata. For instance, when one wants to modify a column of the data according a metavariable.

#### Value

a vector of the same type as var, but of the same length as the number of row in the parent data. As each row of data is matched against metadata for this specific variable.

#### See Also

- behavr to formally create a behavr object
- rejoin to join all metadata with data

```
\#\#\# First, we create some data
library(data.table)
set.seed(1)
data <- data.table(</pre>
                   id = rep(c("A", "B"), times = c(10,26)),
                   t = c(1:10, 5:30),
                   x = rnorm(36), key = "id"
metadata = data.table(id = c("A", "B"),
                       treatment = c("w", "z"),
                       lifespan = c(19, 32),
                       ref_x = c(1, 0),
                       key = "id")
dt <- behavr(data, metadata)</pre>
summary(dt)
#### Subsetting using metadata
dt[xmv(treatment) == "w"]
dt[xmv(treatment) == "w"]
dt[xmv(lifespan) < 30]
#### Allocating new columns using metavariable
# Just joining lifespan (not necessary)
dt[, lif := xmv(lifespan)]
print(dt)
# Anonymously (more useful)
```

12 xmv

```
dt[, x2 := x - xmv(ref_x)]
print(dt)
```
